FIRE AND HYDROGEOMORPHIC PROCESSES

Fire alters hydro-geomorphic processes or rates, increasing runoff and erosion

"...fire can be a potent force for change affecting all systems." (Thomas, 2001)

Photos obtained from Petter Nyman

LANDSCAPE SENSITIVITY

The probability that a geomorphic system will "produce a sensible, recognisable, and persistent response" to a change in system controls or external forcing (Brunsden and Thornes, 1979).

(Phillips, 2009) "...a framework for the assessment of geomorphic changes ... based on the 'four Rs':"

Response – the change in a system

Resistance – the forces resisting change

Resilience – the recovery from change

Recursion (Feedback) – the effect of internal interactions on change

© BUSHFIRE CRC LTD 2012

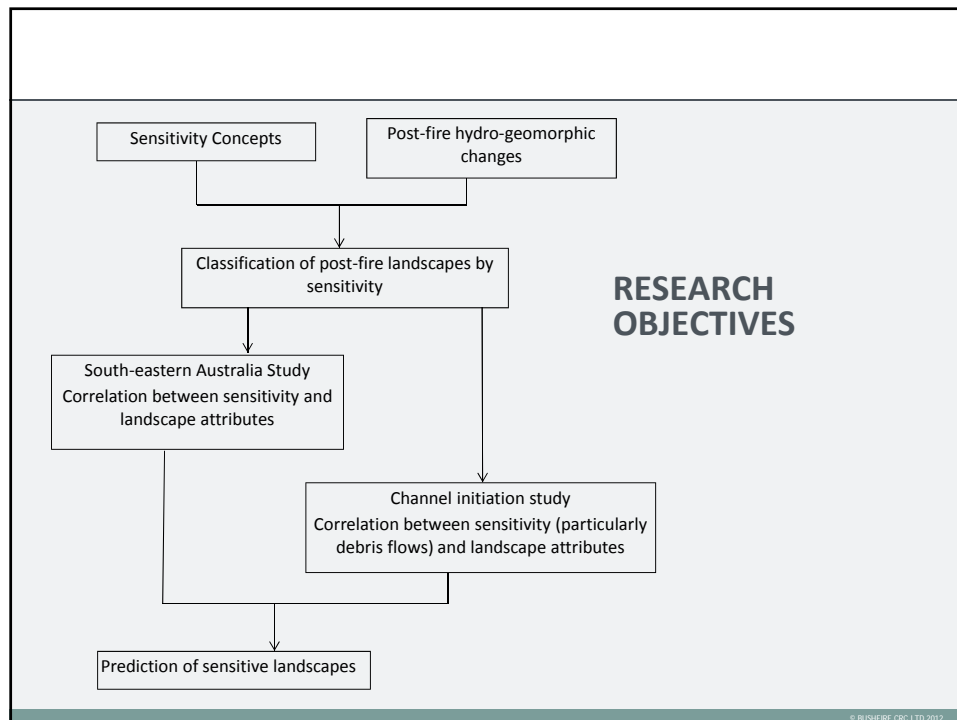

LANDSCAPE SENSITIVITY

The observed response represents the change in a threshold and is dependent on the disturbance, resistance, resilience and feedback.

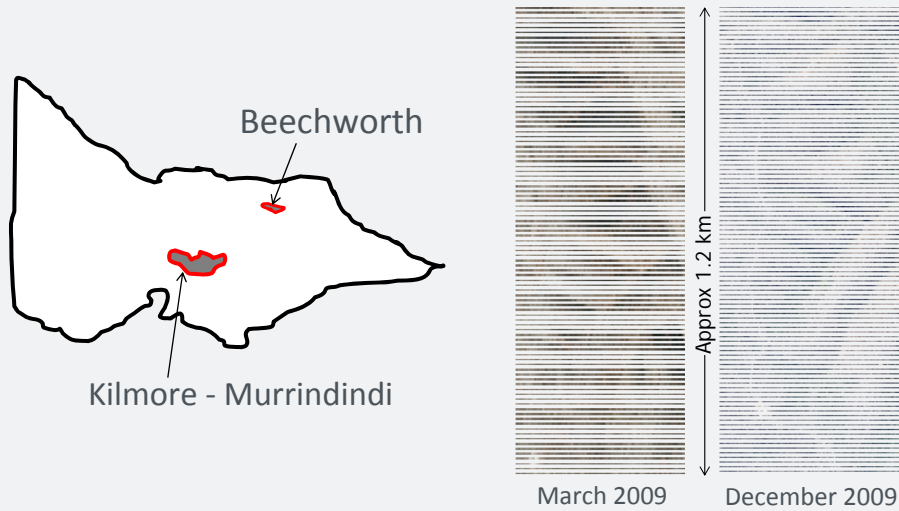

Hypothetical effect of fire on runoff and resistance to erosion (measured as event size required to generate sediment yield)*

QUANTIFYING AND MINIMISING ERROR

1. Need to develop a method of identifying channel initiation points (CIP)
2. Need to be able to define a channel – not as easy as you might think!
3. Need to know the error associated with method
4. Need to minimise error

© BUSHIRE CRC LTD 2012

AERIAL PHOTO IDENTIFICATION METHOD

The channel consists of a single, linear feature that usually extends more or less uninterrupted until its confluence with a creek or river.

From the drainage divide, follow the channel until the first position it meets these criteria for at least 5 m (Figure 1)

The distinction between rills and channels can often be made by noting the shape: rills are often bent (Figure 2).

Figure 1: Search from top down

Figure 2: Rills are curved

© BUSHIRE CRC LTD 2012

AERIAL PHOTO IDENTIFICATION METHOD

A debris deposition, as evidenced by a sudden increase in width/length ratio of the channel, is not a CIP (Figure 3).

Upstream of a fork, each branch is treated as a separate feature that has to qualify the above criteria to identify as a channel. Thus, a fork itself is not automatically a CIP (Figure 4).

Figure 3: Debris deposition

Figure 4: Fork branches are separate

HOW MUCH ERROR WAS THERE?

HOW DID THIS RELATE TO CONTRIBUTING CATCHMENT?

HOW DID THIS RELATE TO CONTRIBUTING SLOPE?

Error in Contributing Area (%) vs. Error in Slope (deg)

© BUSHIRE CRC LTD 2012

MINIMISING ERROR

Error by vegetation class

Figure 3.2: Histogram ($n = 20$, $bis = 10$) for moderately vegetated CPs (40% > [z] > 25%) and its fitted lognormal distribution ($\mu = 2.051$, $\sigma = 0.982$)

SENSITIVITY AND DRYNESS

© BUSHFIRE CRC LTD 2012

THE FUTURE

1. Investigating hydro-geomorphic sensitivity and its causes
2. Modelling/predicting sensitivity levels and risk
3. Develop sensitivity information into useful format for catchment management (mitigation before, during and after a fire)
